

# Simulation Error-Choice Report

2026-05-21

## 1 Overview

This report evaluates multinomial sampling error across cell-type proportions generated from a weighted  $\text{Beta}(\alpha, 1)$  distribution.

For each  $\alpha$ , the workflow:

1. Generates true proportions over  $K$  cell types.
2. Simulates multinomial (no overdispersion) count draws of  $n$  cells,  $B$  times.
3. Computes maximum error across cell types for Absolute Error (AE) and Absolute Relative Error (ARE).
4. Summarizes threshold-based success rates and the cell-type index most frequently driving the maximum error.

## 2 Simulation setup

Table 1: Simulation configuration used in this report.

| Parameter  | Value           |
|------------|-----------------|
| alpha      | 2, 2.5, 3, 4, 5 |
| K          | 10              |
| n          | 1000            |
| B          | 5000            |
| metrics    | AE, ARE         |
| model      | multinomial     |
| tie_method | random          |
| seed       | 260926          |

### 3 True proportions from Beta( $\alpha, 1$ )

The 10 cell types are given proportions equal to the 0.05, 0.15, 0.25,  $\dots$  0.85, 0.95 quantiles from a Beta( $\alpha, 1$ ) distribution and then weighted such that  $\sum p_i = 1$ .

Larger values of  $\alpha$  tend to result in more small-proportion cell types.

Figure 1: Weighted Beta(alpha,1) curves and grid-point proportions by alpha.

Table 2: True proportion values by alpha and cell-type index.

| alpha | index_1 | index_2 | index_3 | index_4 | index_5 | index_6 | index_7 | index_8 | index_9 | index_10 |
|-------|---------|---------|---------|---------|---------|---------|---------|---------|---------|----------|
| 2.0   | 0.01000 | 0.03000 | 0.05000 | 0.07000 | 0.09000 | 0.11000 | 0.13000 | 0.15000 | 0.17000 | 0.19000  |
| 2.5   | 0.00280 | 0.01454 | 0.03129 | 0.05184 | 0.07558 | 0.10212 | 0.13120 | 0.16261 | 0.19620 | 0.23182  |
| 3.0   | 0.00075 | 0.00677 | 0.01880 | 0.03684 | 0.06090 | 0.09098 | 0.12707 | 0.16917 | 0.21729 | 0.27143  |
| 4.0   | 0.00005 | 0.00136 | 0.00628 | 0.01724 | 0.03663 | 0.06688 | 0.11040 | 0.16960 | 0.24688 | 0.34467  |
| 5.0   | 0.00000 | 0.00026 | 0.00197 | 0.00757 | 0.02068 | 0.04614 | 0.09000 | 0.15953 | 0.26319 | 0.41067  |

## 4 Success-rate curves

The success-rate curves show the probability of success (i.e.  $P(\max(\text{error}) < \text{threshold})$ ) for different thresholds.

Figure 2: Success-rate curves by  $\alpha$ , shown separately for AE and ARE.

For the AE, success rate curves are very similar for different true proportions vectors, with a 95% success rate for thresholds between 0.3 and 0.35.

For the ARE, success rate drops down for larger values of  $\alpha$ . This is expected, as larger values of  $\alpha$  increases the number of low-proportion cell types.

Note the jump in success rate for the ARE when threshold  $\tau = 1$ . Since  $\text{ARE} = \text{AE} / p$ , when  $\text{ARE} = 1$ , the AE is equal to the true proportion  $p$ . This happens when the estimated proportion  $\hat{p}$  is equal to 0: i.e. the simulated cell count is 0.

## 5 Argmax histograms

The argmax histograms show the index at which the error is largest (larger indices represent larger true probabilities). In case of a tie, one index is chosen at random.

As expected, AE is largest for larger true proportions  $p$  (closer to 0.5). However, smaller proportions can still contribute to the largest AE.

The ARE is driven mostly by the 2-3 cell types with the smallest proportion. Note for  $\alpha = 5$ , the 2nd smallest proportion actually has the largest ARE, most of the time. The smallest proportion will often have a simulated cell count of 0, resulting in an ARE of exactly 1. The second smallest proportion then has a possibility to show a larger ARE.

Figure 3: Argmax histograms by alpha for AE maximum-error indices.

Figure 4: Argmax histograms by alpha for ARE maximum-error indices.

## 6 Keep highest proportion fixed, vary other proportions

### 6.1 Simulation proportions

The highest proportions are kept constant (0.2, 0.3, 0.4, 0.5, 0.6), with the other proportions varying based on a beta distribution (as before). Some values of alpha would lead to some of the remaining proportions to be larger than the maximal proportion and are thus excluded.

Figure 5: Grid-point proportions by alpha (columns), and maximal proportions (rows).

Table 3: True proportion values by alpha, maximal proportion and cell-type index.

| alpha | p_max | index_1 | index_2 | index_3 | index_4 | index_5 | index_6 | index_7 | index_8 | index_9 | index_10 |
|-------|-------|---------|---------|---------|---------|---------|---------|---------|---------|---------|----------|
| 2.0   | 0.2   | 0.00889 | 0.02889 | 0.04889 | 0.06889 | 0.08889 | 0.10889 | 0.12889 | 0.14889 | 0.16889 | 0.2      |
| 2.0   | 0.3   | 0.00778 | 0.02528 | 0.04278 | 0.06028 | 0.07778 | 0.09528 | 0.11278 | 0.13028 | 0.14778 | 0.3      |
| 2.5   | 0.3   | 0.00217 | 0.01272 | 0.02800 | 0.04684 | 0.06866 | 0.09309 | 0.11988 | 0.14883 | 0.17981 | 0.3      |
| 3.0   | 0.3   | 0.00058 | 0.00614 | 0.01759 | 0.03493 | 0.05815 | 0.08726 | 0.12226 | 0.16315 | 0.20993 | 0.3      |
| 4.0   | 0.3   | 0.00004 | 0.00133 | 0.00643 | 0.01799 | 0.03865 | 0.07104 | 0.11782 | 0.18162 | 0.26508 | 0.3      |
| 2.0   | 0.4   | 0.00667 | 0.02167 | 0.03667 | 0.05167 | 0.06667 | 0.08167 | 0.09667 | 0.11167 | 0.12667 | 0.4      |
| 2.5   | 0.4   | 0.00186 | 0.01090 | 0.02400 | 0.04015 | 0.05885 | 0.07979 | 0.10275 | 0.12757 | 0.15412 | 0.4      |

## 6.2 Results

The highest proportion (closest to 0.5) has most often the largest AE. Additionally, for a given maximal proportion, the number of times this maximal proportion results in the largest AE seems to be stable over all values of alpha.

This could be repeated with a constant minimal proportion to check the effect on ARE.

Figure 6: Argmax histograms by alpha (columns) and maximal proportion (rows) for AE maximum-error indices.

## 7 Next steps

- Repeat with overdispersion (dirichlet multinomial)
- Repeat with a fixed minimal proportion and check the effect on the ARE
- Find a cutoff for when to choose AE vs ARE
  - Idea: for a given threshold for AE and ARE, which cutoff for  $\hat{p}$  maximizes the success-rate
- Hierarchical distributions
  - Idea: “parent” has a certain proportion,
  - “Daughter” cell types have (uniform) distribution
  - How does this affect the distribution of error metrics?
